**Question Set 2**

1 Bread contains a mixture of polypeptides known as gluten.

Gluten consists of two types of polypeptide: gliadins and glutenins.

(a) (i) The table below contains statements about the structures of gluten polypeptides.

In the boxes next to each statement, write the level of protein structure (primary, secondary, tertiary, or quaternary) to which the statement refers.

| Statement   | Level of protein structure |
|---|----------------------------|
| Short $\alpha$ -helical sections are present in both polypeptides because of their high proline content |                            |
| Intermolecular bonds form between glutenin and gliadin polypeptides                                     |                            |
| Up to 45% of the amino acids in gliadins are glutamine  |                            |
| Hydrophobic amino acids such as glutamine and proline are not found on the surface of gluten proteins   |                            |

[2]

(ii) Coeliac disease is caused by an immune reaction to gliadins in a person's digestive system. The immune system produces antibodies that bind to part of the gliadin polypeptides, which causes inflammation.

Some people who stop eating foods that contain gluten still occasionally experience the symptoms of coeliac disease.

What can you conclude about:

- the structure of the antibody that causes coeliac disease; and
- what the antibody binds to when producing the symptoms of coeliac disease?

[2]

- (b) Gluten helps to trap carbon dioxide within bread dough. This enables bread to rise when it is baked.

The carbon dioxide is produced by baker's yeast, *Saccharomyces cerevisiae*. This species of yeast is able to convert ethanol to acetyl CoA at low glucose concentrations.

Fig. 2 shows the oxygen consumption and carbon dioxide production of a population of *S. cerevisiae* grown in batch culture. The population was provided with glucose as their only initial source of carbon.

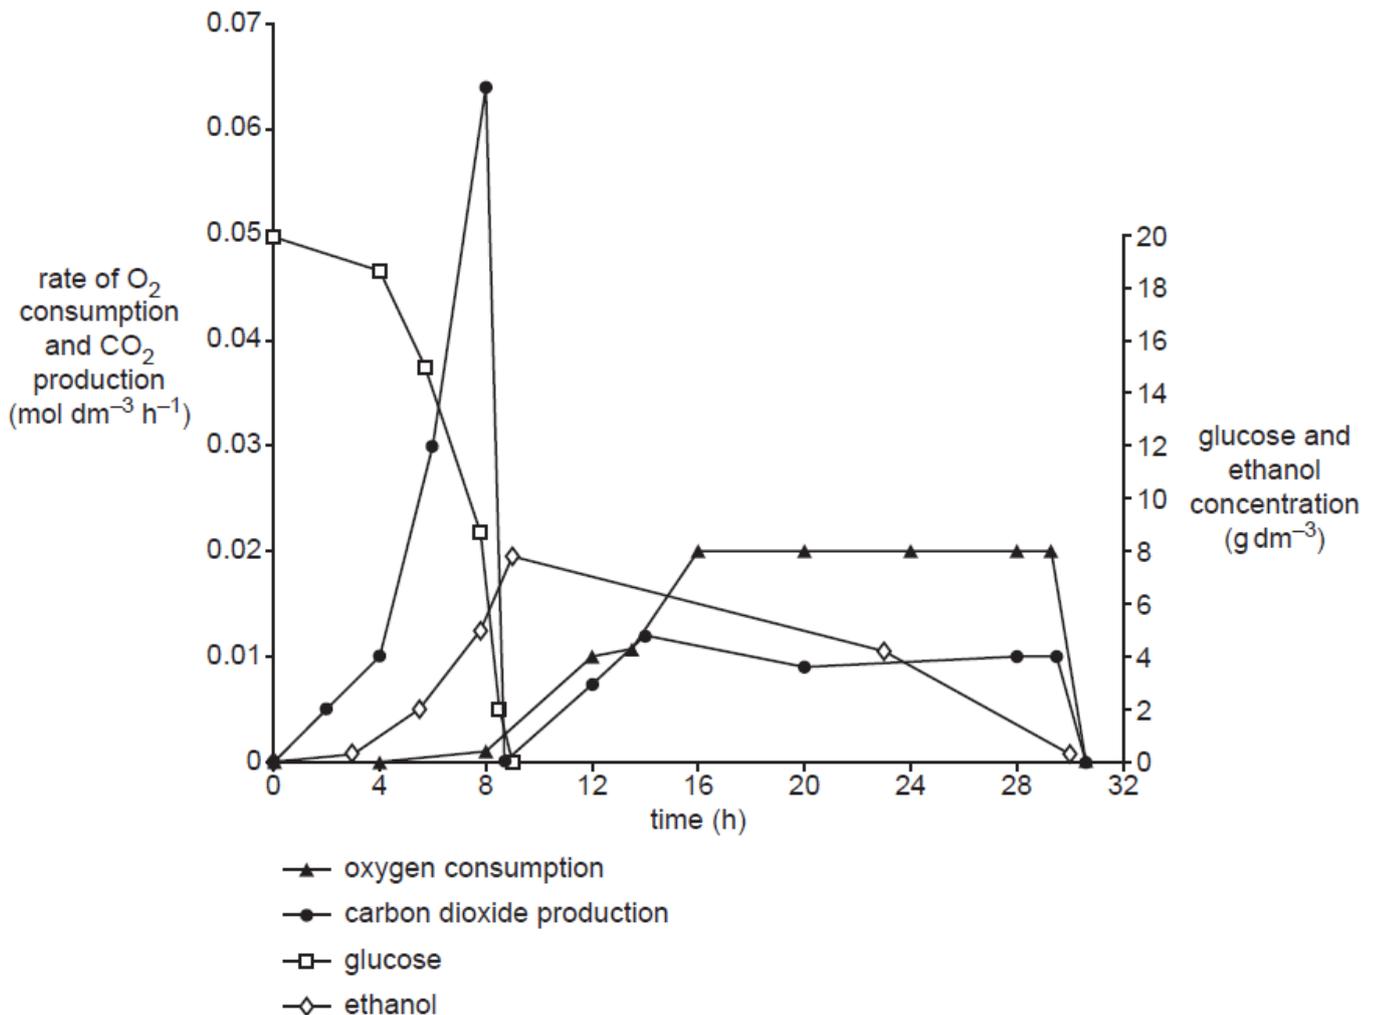

Fig. 2

- (i) Suggest and explain what conclusions can be drawn from Fig. 2 about the factors that affected the rate and type of respiration carried out by *S. cerevisiae* in this batch culture.

[3]

- (ii) Describe **two** practical considerations to ensure the *S. cerevisiae* population grows successfully when the initial culture is established.

[2]

- (iii) Scientists wanted to estimate the number of yeast cells in a 25 cm<sup>3</sup> solution of *S. cerevisiae*. They carried out the following two dilutions:
- 1 cm<sup>3</sup> of the original solution was mixed with 9 cm<sup>3</sup> of nutrient solution to make solution 2.
  - 1 cm<sup>3</sup> of solution 2 was mixed with 9 cm<sup>3</sup> of nutrient solution to make solution 3.

The scientists transferred 0.1 cm<sup>3</sup> of solution 3 onto an agar plate. 15 separate colonies grew on the plate.

Calculate the number of yeast cells in the original 25 cm<sup>3</sup> solution.

Express your answer in standard form to **three** significant figures. Show your working.

Answer.....[2]

- (iv) A group of students were designing an experiment to investigate the effect of temperature on the respiration rate of *S. cerevisiae*.

Their planned method included the following:

- *S. cerevisiae* yeast suspension will be divided into six equal volumes to form the experimental groups.
- Six temperatures will be tested: 15 °C, 20 °C, 25 °C, 30 °C, 35 °C and 40 °C.
- Beakers of *S. cerevisiae* will be placed in water baths to control the temperature.
- Respiration rate will be measured by using a pH probe to monitor changes in the pH of the suspensions.
- The experiment will be repeated four times.

Evaluate whether the students' method is likely to produce **valid** results. [3]

- (v) The students used a Student's *t*-test to compare the results at 30 °C and 35 °C. They calculated a *t* value of 2.200.

The critical value for  $p = 0.05$  is 2.306.

Assuming their final method was valid, what can the students conclude from the result of the *t*-test? [1]
